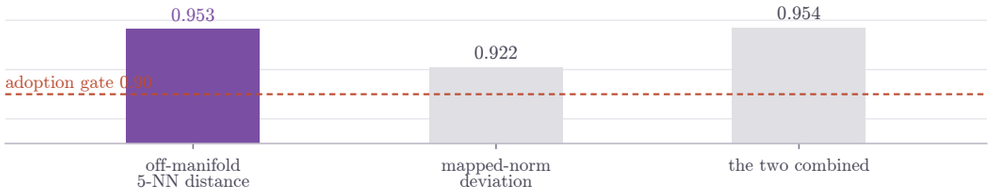
what the browser bridge's 38.6 % region disagreement is made of

1 439 flips over 3 731 held-out syllables. Tie-adjusted agreement 0.91; species-level agreement 0.781 against chance 0.033. The addressable loss is at most 2.6 % of rows, so no better map class was pursued.

eight of 45 held-out sessions carry 22.9 % of that loss, and separate cleanly



The browser can compute the winning signal from the 28-d side alone, and a shipped cloud of 256 random anchors holds AUC $\geq$ 0.92 for 28 kB. Using it as a lever - raising the remaining rows' agreement by 5 points - failed at +3.5, so the pre-registered fallback fired and it ships as an honesty gate. End-to-end debug build; debug-scale.
