

Pale, thin: Pearson. Solid, thick: Spearman. Both metrics point away from zero only because the mel target is the replacement. Not an instrument artefact: the recomputed cosine reproduces the stored median Pearson 0.921, and the two distortion metrics agree with each other at 0.925. $n = 200$ utterances.

Blended at weight 0.5 the mel target wins 25 of 80 types, with a median ΔMCD of exactly 0.0 dB and a maximum cosine loss of 0.120. Seven of ten had won at probe scale.
